

ABELIAN SURFACES ADMITTING AN (l, l) -ENDOMORPHISM

REINIER BRÖKER, KRISTIN LAUTER, AND MARCO STRENG

ABSTRACT. We give a classification of all principally polarized abelian surfaces that admit an (l, l) -isogeny to themselves, and show how to compute all the abelian surfaces that occur. We make the classification explicit in the simplest case $l = 2$. As part of our classification, we also show how to find all principally polarized abelian surfaces with multiplication by a given imaginary quadratic order.

1. INTRODUCTION

For a prime l , the l -th *modular polynomial* $\Phi_l \in \mathbf{Z}[X, Y]$ is a model for the modular curve $Y_0(l)$ parametrizing elliptic curves together with an isogeny of degree l . This polynomial is used in various algorithms, including the ‘Schoof-Atkin-Elkies’ algorithm (see [14]) to count the number of points on an elliptic curve $E/\mathbf{F}_p$. If we specialize Φ_l in $Y = X$ we get a *univariate* polynomial $\Phi_l(X, X) \in \mathbf{Z}[X]$ whose roots are the j -invariants of the elliptic curves $E/\mathbf{C}$ that admit an endomorphism of degree l . There is a close link between $\Phi_l(X, X)$ and the *Hilbert class polynomials* $H_{\mathcal{O}}$ of imaginary quadratic orders $\mathcal{O}$. More precisely, we have

$$(1.1) \quad \Phi_l(X, X) = \prod_{\mathcal{O}} H_{\mathcal{O}}(X)^{e(\mathcal{O})}$$

where the product ranges over all imaginary quadratic orders $\mathcal{O}$ that contain an element of norm l . The exponent

$$e(\mathcal{O}) = \#(\{\alpha \in \mathcal{O} \text{ of norm } l\} / \mathcal{O}^*) \in \mathbf{Z}_{>0}$$

measures how many elements of norm l there are in $\mathcal{O}$. One of the applications of (1.1) is a proof that $H_{\mathcal{O}}(X)$ has integral coefficients.

In this article we investigate an analogue of equation (1.1) for abelian surfaces. The appropriate analogue of an isogeny of degree l is an (l, l) -isogeny. If A and B are abelian surfaces with principal polarizations φ_A and φ_B , then an (l, l) -isogeny

$$\lambda : (A, \varphi_A) \rightarrow (B, \varphi_B)$$

is an isogeny $\lambda : A \rightarrow B$ such that we have $\varphi_A \circ [l] = \widehat{\lambda} \circ \varphi_B \circ \lambda$, with $\widehat{\lambda}$ the dual of λ . Let $\mathcal{M}_2^{(l, l)} \subset \mathcal{A}_2$ be the reduced subvariety of principally polarized abelian surfaces (A, φ_A) admitting an (l, l) -isogeny $(A, \varphi_A) \rightarrow (A, \varphi_A)$. The variety $\mathcal{M}_2^{(l, l)}$ is the natural analogue of the zero set of $\Phi(X, X)$. The goal in this article is to identify the irreducible subvarieties of $\mathcal{M}_2^{(l, l)}$, which is the natural analogue of equality (1.1).

2000 *Mathematics Subject Classification*. Primary 14J10.

The research for this paper was done during an internship of the third-named author at Microsoft Research.

While the moduli space of elliptic curves is 1-dimensional, the moduli space $\mathcal{A}_2$ of principally polarized abelian surfaces is 3-dimensional. Its function field is generated by three *Igusa invariants*

$$j_i : \mathcal{A}_2 \rightarrow \mathbf{P}^1(\mathbf{C})$$

as e.g. defined in [6]. One can define three *modular polynomials* $P_l, Q_l, R_l \in \mathbf{Q}(X_1, X_2, X_3)[Y]$ for abelian surfaces using these Igusa functions, see e.g. [4, Sec. 4].

As a first idea, one might let $W_l \subset \mathbf{C}[X_1, X_2, X_3, Y_1, Y_2, Y_3]$ be the ideal generated by the numerators of

$$P_l(X_1, X_2, X_3, Y_1), \quad Y_2 - Q_l(X_1, X_2, X_3, Y_1), \quad Y_3 - R_l(X_1, X_2, X_3, Y_1)$$

and view this as the analogue of Φ_l . However, the functions j_i do *not* give a bijection

$$\mathcal{A}_2 \rightarrow \mathbf{P}^1(\mathbf{C})^3,$$

even when we restrict the domain to the moduli space of Jacobians of curves and consider the resulting map to $\mathbf{C}^3$. Because of this and other reasons, the space described by W_l is very unnatural. However, the space W_l can be very useful in computational applications, as its intersection with $X_i = Y_i$, pulled back to $\mathcal{A}_2$, contains $\mathcal{M}_2^{(l,l)}$. We use generators for W_2 computed by Dupont in his thesis [5] in Section 7.

We will show that $\mathcal{M}_2^{(l,l)}$ consists of a finite set of explicitly computable *Humbert surfaces*, *Shimura curves* and *CM-points*. In particular, the space $\mathcal{M}_2^{(l,l)}$ is 2-dimensional. The CM-points are a direct analogue of the Hilbert class polynomials for genus 1. Our main result, proved in Section 4.4, is the following.

Theorem 1.1. *Let l be a prime number. The variety $\mathcal{M}_2^{(l,l)}$ is the union of the following list of varieties:*

- (1) *Either one or two irreducible Humbert surfaces, depending on whether $l \equiv 3 \pmod{4}$ or not as in Corollary 4.2.*
- (2) *for every imaginary quadratic integer x of norm l and trace less than $2\sqrt{l}$, all Shimura curves corresponding to $\mathbf{Z}[x]$. The correspondence between $\mathbf{Z}[x]$ and Shimura curves is given in Theorem 3.6.*
- (3) *for every imaginary quadratic integer x of norm l and trace less than $2\sqrt{l}$, all CM-points corresponding to $\mathbf{Z}[x]$. The correspondence between $\mathbf{Z}[x]$ and CM-points is given in Theorem 3.6.*
- (4) *for every algebraic integer x of degree 4 with the property that all complex absolute values of x are equal to $\sqrt{l}$, the CM-points corresponding to the order $\mathbf{Z}[x, \bar{x}] \subset K = \mathbf{Q}[x]$. This correspondence is given in Theorem 3.6.*
- (5) *for every pair of integers t_1, t_2 such that $-2\sqrt{l} < t_2 < t_1 < 2\sqrt{l}$, the points corresponding to finitely many principally polarized abelian surfaces that are (n, n) -isogenous to $E_1 \times E_2$. Here, n divides $t_1 - t_2$ and E_i is an elliptic curve whose endomorphism ring contains the quadratic order of discriminant $t_i^2 - 4l$.*

We can make Theorem 1.1 more explicit in the simplest case $l = 2$. It turns out for instance that the Shimura curves listed as case (2) in fact lie on the Humbert surface of case (1). More precisely, we will prove the following theorem.

Theorem 1.2. *The variety $\mathcal{M}_2^{(2,2)}$ is the union of the Humbert surface of discriminant 8, which is irreducible, and a finite set of CM-points listed in Section 7.*

The organization of this article is as follows. Section 2 gives background on abelian surfaces and isogenies. Section 3 describes the moduli space of abelian surfaces with *endomorphism ring structure*. Section 4 gives the proof of Theorem 1.1. Section 5 examines the endomorphism rings for each of the cases occurring in the Theorem. Section 6 recalls explicit glueing techniques that are used in Section 7 where we compute all irreducible components of $\mathcal{M}_2^{(2,2)}$ in terms of Igusa invariants.

2. BACKGROUND

In this section we recall some background on complex abelian surfaces and (l, l) -isogenies. We state the results in terms of Riemann forms, but note that most can be generalized to fields of arbitrary characteristic.

Let V be a 2-dimensional complex vector space, and let $\Lambda \subset V$ be a full lattice. Any form $E : \Lambda \times \Lambda \rightarrow \mathbf{Z}$ can be extended to a form $E : V \times V \rightarrow \mathbf{R}$, and we call E a *Riemann form* if the form $H(x, y) = E(ix, y) + iE(x, y)$ is Hermitian and positive definite. We say that the quotient V/Λ is a (complex) *abelian surface* if $\Lambda \subset V$ admits a Riemann form.

For an abelian surface $A = V/\Lambda$, we define its dual as $A^\vee = V^\vee/\Lambda^\vee$ with

$$\begin{aligned} V^\vee &= \{f : V \rightarrow \mathbf{C} \mid f(av) = \bar{a}f(v), f(v+w) = f(v) + f(w)\}, \\ \Lambda^\vee &= \{f \in V^\vee \mid \text{Im}(f(\Lambda)) \subset \mathbf{Z}\}. \end{aligned}$$

A Riemann form E on A determines a homomorphism

$$(2.1) \quad \varphi_E : A \rightarrow A^\vee$$

by $\varphi_E(x) = H(x, \cdot)$ for $x \in V$. The map φ_E is called a *polarization* and the pair (E, φ_E) a *polarized abelian variety*. We say that (A, φ_E) is *principally polarized* if φ_E is an isomorphism, or, equivalently, if $\det E = 1$ on $\Lambda \times \Lambda$.

Lemma 2.1. *Let $A = V/\Lambda$ be an abelian surface with Riemann form E . Then there is exactly one map $' : \text{End}(A) \rightarrow \text{End}(A)$ with the property $E(yu, v) = E(u, y'v)$ for all u, v . This map is a ring involution.*

Proof. This follows immediately from the defining properties of E . $\square$

Definition 2.2. *The map $'$ in Lemma 2.1 is called the Rosati-involution associated to the polarization φ_E .*

A surjective morphism $f : A \rightarrow B$ between abelian surfaces is called an *isogeny* if it has finite kernel. The polarization φ_E occurring in (2.1) is an example of an isogeny. If E' is a Riemann form on B , then an isogeny $f : A \rightarrow B$ induces a Riemann form

$$f^*E' : (u, v) \mapsto E'(f(u), f(v))$$

on A .

Definition 2.3. *For a positive integer n , an (n, n) -isogeny $f : (A, E) \rightarrow (B, E')$ is an isogeny $A \rightarrow B$ such that*

- (1) $f^*E' = nE$ holds and
- (2) the kernel of f is contained in $A[n]$.

For prime n , the second item is automatic from the first, and the definition is easily seen to be equivalent to the definition given in the introduction.

Lemma 2.4. *Let (A, φ_E) be a principally polarized abelian surface that admits an (n, n) -isogeny x to itself. Then we have $x'x = [n]$.*

Proof. This follows from the fact that the equality $E(u, x'xv) = E(xu, xv) = nE(u, v) = E(u, nv)$ holds for all u, v . $\square$

The kernel of an (n, n) -isogeny $x : (A, E) \rightarrow (B, E')$ is a subgroup of the n -torsion $A[n]$ with additional structure. To analyze it, we define the *Weil pairing* $e_n : A[n] \times A[n] \rightarrow \mathbf{C}^*[n]$ by

$$e_n(u, v) = \exp(2\pi i n E(u, v))$$

for $u, v \in \frac{1}{n}\Lambda \subset V$. We say that a subgroup $G \subset A[n]$ is *isotropic* (with respect to the Weil pairing) if e_n restricts to the trivial form on $G \times G$. We say that G is *maximally isotropic* if it is not strictly contained in another isotropic subgroup.

Lemma 2.5. *Let $x : (A, E) \rightarrow (B, E')$ be an (n, n) -isogeny. Then the kernel of x is maximally isotropic with respect to the Weil pairing. Furthermore, every maximally isotropic subgroup $G \subset A[n]$ arises as the kernel of an (n, n) -isogeny.*

If n is prime, then there are exactly $(n^4 - 1)/(n - 1)$ such subgroups.

Proof. The first two statements follow from [16, Prop. 16.8]. The last statement follows from the proof of [4, Lemma 6.1]. $\square$

We will need a few properties of the analytic and rational representation of an (n, n) -isogeny. We recall the basic concepts in the remainder of this section. Let $A_1 = \mathbf{C}^2/\Lambda_1$ and $A_2 = \mathbf{C}^2/\Lambda_2$ be two principally polarized abelian surfaces, and let $f : A_1 \rightarrow A_2$ be a homomorphism. We can uniquely lift f to a $\mathbf{C}$ -linear map $F : \mathbf{C}^2 \rightarrow \mathbf{C}^2$ with $F(\Lambda_1) \subseteq \Lambda_2$. The natural map

$$\rho_a : \text{Hom}(A_1, A_2) \rightarrow \text{Hom}_{\mathbf{C}}(\mathbf{C}^2, \mathbf{C}^2)$$

sending f to F is called the *analytic representation* of $\text{Hom}(A_1, A_2)$. By restricting F to the lattice Λ_1 , we get a $\mathbf{Z}$ -linear map F_{Λ_1} that induces F . The natural map

$$\rho_r : \text{Hom}(A_1, A_2) \rightarrow \text{Hom}_{\mathbf{Z}}(\Lambda_1, \Lambda_2)$$

sending f to F_{Λ_1} is called the *rational representation* of $\text{Hom}(A_1, A_2)$. We use the same notation and terminology for the $\mathbf{Q}$ -linear extension of ρ_a and ρ_r .

For $f \in \text{End}_{\mathbf{Q}}(A) = \text{End}(A) \otimes_{\mathbf{Z}} \mathbf{Q}$, let P_f^a be the characteristic polynomial of the analytic representation $\rho_a(f)$ of f . Likewise, we get P_f^r for the rational representation of f . Explicitly, we have

$$P_f^a = \det(X \text{id}_{\mathbf{C}^2} - \rho_a(f)) \in \mathbf{C}[X] \quad \text{and} \quad P_f^r = \det(X \text{id}_{\Lambda} - \rho_r(f)) \in \mathbf{Q}[X].$$

The polynomial P_f^a is quadratic, and P_f^r has degree 4. The following lemma gives the relation between the analytic and the rational representation.

Lemma 2.6. *Let $A = \mathbf{C}^2/\Lambda$ be a principally polarized abelian surface, and let $f \in \text{End}_{\mathbf{Q}}(A)$ be given. Then we have*

- (a) $P_f^r = P_f^a \cdot \overline{P_f^a}$ and
- (b) $P_{f'}^a = \overline{P_f^a}$

where $\overline{}$ denotes complex conjugation and $'$ denotes the Rosati-involution. The polynomial P_f^r has integer coefficients if f is an endomorphism of A .

Proof. This follows immediately from [2, Prop. 5.1.2] and [2, Lemma 5.1.4]. $\square$

3. MODULI SPACES OF ABELIAN SURFACES WITH ENDOMORPHISM STRUCTURE

For a principally polarized abelian surface $A = (A, \varphi_E)$ with (n, n) -isogeny x to itself, the algebra $K = \mathbf{Q}[x]$ is a subalgebra of the endomorphism algebra $\text{End}_{\mathbf{Q}}(A)$. We distinguish between the case that K is / is not a field.

3.1. K is not a field. Using Lemma 2.6 we analyze the structure of $K = \mathbf{Q}[x]$ if K is not a field. The result is the following lemma.

Lemma 3.1. *Let x be an endomorphism of a principally polarized abelian surface $A/\mathbf{C}$ with $xx' = l$ for some prime l . Let $K = \mathbf{Q}[x] \subseteq \text{End}(A) \otimes \mathbf{Q}$ and assume that K is not a field. Then we have $P_x^a = (X - \beta_1)(X - \beta_2)$ for some pair of imaginary quadratic integers $\beta_1, \beta_2 \in \mathbf{C}$ of absolute value $\sqrt{l}$ and non-equal trace. The map*

$$x \mapsto (\beta_1, \beta_2)$$

gives an isomorphism $K \xrightarrow{\sim} \mathbf{Q}(\beta_1) \times \mathbf{Q}(\beta_2)$. Furthermore, there exist elliptic curves E_1, E_2 , a positive integer $n \mid (\text{Tr}\beta_1 - \text{Tr}\beta_2) \neq 0$ and an (n, n) -isogeny

$$\lambda : E_1 \times E_2 \rightarrow A$$

with the following properties:

- (1) *the endomorphism ring of E_i contains $\mathbf{Z}[\beta_i]$ for $i = 1, 2$;*
- (2) *we have $x \circ \lambda = \lambda \circ (\beta_1, \beta_2)$.*

Proof. Choose a basis of $\mathbf{C}^2$ such that the analytic representation of x is upper-triangular, say

$$\rho_a(x) = \begin{pmatrix} \beta_1 & * \\ 0 & \beta_2 \end{pmatrix}$$

with β_1, β_2 in $\mathbf{C}$. Note that $\rho_a(x') = \rho_a(lx^{-1})$ is also upper-triangular, say

$$\rho_a(x') = \begin{pmatrix} \gamma_1 & * \\ 0 & \gamma_2 \end{pmatrix}.$$

As β_1 and β_2 are roots of P_x^r , they are algebraic integers. We let g be the minimal polynomial of β_1 . We claim that γ_2 is not an algebraic conjugate of β_1 , i.e., that $g(\gamma_2) \neq 0$ holds. Indeed: otherwise we have $\text{Tr}(g(x)g(x')) = \text{Tr}(g(x)g(x')) = 0$ and because $'$ is positive definite by [2, Thm. 5.1.8], we find $g(x) = 0$, contradicting the assumption that K is not a field.

By Lemma 2.6(b), we have $\{\gamma_1, \gamma_2\} = \{\overline{\beta_1}, \overline{\beta_2}\}$, so the claim above yields $\gamma_1 = \overline{\beta_1}, \gamma_2 = \overline{\beta_2}$, and that β_1 and β_2 are not algebraic conjugates. It follows from $\beta_i \overline{\beta_i} = \beta_i \gamma_i = l$ that β_i has absolute value $\sqrt{l}$ for $i = 1, 2$. Since β_1 and β_2 are non-conjugate imaginary quadratic integers with the same norm, they have distinct trace. It follows that $x \mapsto (\beta_1, \beta_2)$ gives an isomorphism

$$K = \mathbf{Q}[X]/(P_x^r) \xrightarrow{\sim} \mathbf{Q}(\beta_1) \oplus \mathbf{Q}(\beta_2).$$

To prove the remainder of the lemma, put

$$e = x + x' - \text{Tr}\beta_1 \in \text{End}(A),$$

and let $k = \text{Tr}(\beta_2) - \text{Tr}(\beta_1) \neq 0$. The relation $e^2 = ke$ holds on the two β_i -eigenspaces V_i of the analytic representation of x in $\mathbf{C}^g$ and hence on A . We see that $e/k \in \text{End}_{\mathbf{Q}}(A)$ satisfies

$$(e/k)' = e/k \quad \text{and} \quad (e/k)^2 = e/k,$$

i.e., e/k is a symmetric idempotent in the endomorphism algebra. Let $n \mid k$ be the smallest positive integer such that ne/k is an endomorphism and let E_1 be its image. It is clear that $E_1 = V_2/(V_2 \cap \Lambda)$ is an elliptic curve inside $A = \mathbf{C}^g/\Lambda$.

The element $1 - e/k$ is also a symmetric idempotent, and we let E_2 be the image of $n(1 - e/k) \in \text{End}(A)$. The subvariety E_2 is also an elliptic curve, and it is the complementary subvariety of E_1 in A . We claim that the ‘addition map’ $\lambda : E_1 \times E_2 \rightarrow A$ given by

$$(x, y) \mapsto x + y$$

is an (n, n) -isogeny.

To prove the claim, we note that λ is an isogeny by a corollary to Poincaré’s reducibility theorem [2, Cor. 5.3.6]. Using the isomorphism $\text{End}^s(A) \rightarrow \text{NS}(A)$ between the symmetric endomorphisms of A and its Néron-Severi group, see e.g. [2, Thm. 5.2.4], we see that the restriction of the polarization φ_A of A to E_i is the polarization $\varphi_{E_i} \circ [n]$.

It remains to show that $\ker \lambda$ is contained in $(E_1 \times E_2)[n]$. This follows from the argument in [11, Sec. 2] showing that $\ker \lambda$ is isomorphic to both $E_1[n]$ and $E_2[n]$. $\square$

If the ring $\mathbf{Z}[\beta]$ is contained in the endomorphism ring of E , then we automatically have $E \cong \mathbf{C}/\mathfrak{a}$ for a $\mathbf{Z}[\beta]$ -ideal $\mathfrak{a}$. It is well understood how to compute an algebraic model of $\mathbf{C}/\mathfrak{a}$, we refer to [6] for details. Once the finitely many candidates for E_1 and E_2 are computed, there are only finitely many possibilities for n and λ , hence for A .

3.2. K is a field. We continue with the case that $K = \mathbf{Q}[x]$ is a field. The following lemma restricts the structure of $K/\mathbf{Q}$.

Lemma 3.2. *Let A and $K = \mathbf{Q}[x]$ be as above. Suppose that K is a field. Then K is either a quadratic field or a degree-4 CM-field, i.e., a degree-4 number field K such that complex conjugation induces the same automorphism of K for every embedding $K \rightarrow \mathbf{C}$. In both cases, the Rosati-involution $'$ is complex conjugation on K .*

Proof. See [2, Sec. 5.5]. $\square$

Example 3.3. *Let $\mathbf{Q}[x]$ be a quadratic field over $\mathbf{Q}$ and suppose that we have $x\bar{x} = l$. Then the trace of x is at most $2\sqrt{l}$. In particular, for $l = 2$, we have $x \in \{\sqrt{-2}, \frac{1}{2}(1 + \sqrt{-7}), 1 + \sqrt{-1}, \sqrt{2}\}$ up to sign and complex conjugation.*

By Lemma 3.2, the field K is quadratic or a degree-4 CM-field. In the former case, let $m(K) = 2$ and in the latter case let $m(K) = 1$. Writing $A = V/\Lambda$, there exists an isomorphism

$$\Lambda \otimes \mathbf{Q} \xrightarrow{\sim} K^{m(K)}.$$

The lattice Λ has a natural $\mathbf{Z}[x]$ -module structure, and, under an isomorphism as above, corresponds to a $\mathbf{Z}[x]$ -submodule $\mathcal{M}$ of $K^{m(K)}$ of rank 4 over $\mathbf{Z}$.

Lemma 3.4. *Let $A, K, ', \mathcal{M}$ be as above. Then there exists a matrix $T \in \text{GL}_2(K)$ satisfying $(T')^T = -T$ such that $E(u, v) = \text{Tr}_{K/\mathbf{Q}}(u^T T v')$ is the Riemann form inducing the principal polarization on A .*

Proof. See [2, Prop. 9.2.3.] and [2, Prop. 9.6.5]. $\square$

Example 3.5. If K is a real quadratic field, then $'$ is the identity on K . The matrix T therefore equals

$$\begin{pmatrix} 0 & r \\ -r & 0 \end{pmatrix}$$

for some $r \in K^*$.

Lemma 3.4 tells us that the surface A yields a pair $(\mathcal{M}, T)$ consisting of a $\mathbf{Z}[x]$ -submodule $\mathcal{M}$ of $K^{m(K)}$ and a matrix $T \in \mathrm{GL}_2(K)$ such that the $\mathbf{Q}$ -bilinear form $K^{m(K)} \times K^{m(K)} \rightarrow \mathbf{Q}$ given by $(u, v) \mapsto \mathrm{Tr}_{K/\mathbf{Q}}(u^T T v')$ restricts to a $\mathbf{Z}$ -bilinear form $\mathcal{M} \times \mathcal{M} \rightarrow \mathbf{Z}$ of determinant 1. Conversely, for a fixed algebraic integer x and for a fixed pair $(\mathcal{M}, T)$, Shimura gives an explicit complex analytic description [2, Sec. 9.8] of the subspace $S(\mathcal{M}, T) \subset \mathcal{A}_2$ of principally polarized abelian surfaces belonging to this pair $(\mathcal{M}, T)$. The following theorem states that $S(\mathcal{M}, T)$ is an irreducible variety and gives its dimension.

Theorem 3.6. Let K be either a quadratic field or a degree-4 CM-field and let $\mathbf{Z}[x]$ be an order in K . Let $\mathcal{M}$ be a $\mathbf{Z}[x]$ -submodule of $K^{m(K)}$ of rank $m(K)$ and $T \in \mathrm{GL}_2(K)$ a matrix satisfying $(T')^T = -T$. Suppose that the $\mathbf{Q}$ -bilinear form $K^{m(K)} \times K^{m(K)} \rightarrow \mathbf{Q}$ given by $(u, v) \mapsto \mathrm{Tr}_{K/\mathbf{Q}}(u^T T v')$ restricts to a $\mathbf{Z}$ -bilinear form $\mathcal{M} \times \mathcal{M} \rightarrow \mathbf{Z}$ of determinant 1. Let $S(\mathcal{M}, T) \subset \mathcal{A}_2$ be the subspace of all principally polarized abelian surfaces that correspond to $(\mathcal{M}, T)$. Then the following holds:

- if K is real quadratic, then $S(\mathcal{M}, T)$ is an irreducible (Humbert) surface,
- if K is imaginary quadratic and $\det(T) > 0$, then $S(\mathcal{M}, T)$ is an irreducible (Shimura) curve. For any abelian surface A in $S(\mathcal{M}, T)$, the polynomial P_x^a is the minimal polynomial of x ;
- if K is imaginary quadratic and $\det(T) < 0$, then $S(\mathcal{M}, T)$ consists of one abelian surface A , which is isogenous as an unpolarized surface to a product $E \times E$ of an elliptic curve with itself. In this case we have $\mathrm{End}_{\mathbf{Q}}(E) = K$ and $P_x^a = (X - \beta)^2$ for some $\beta \in \mathbf{C}$;
- if K is a degree-4 CM-field, then $S(\mathcal{M}, T)$ consists of one abelian surface.

Proof. All cases are special cases of the theory in [2, §9.6], except the real quadratic case, which is a special case of [2, §9.2]. $\square$

4. FINDING ALL ABELIAN SURFACES

In this section we show how to explicitly compute the pairs $(\mathcal{M}, T)$ that occur in the first four cases of Theorem 1.1. Our computations yield the proof of the Main Theorem as well.

Two pairs $(\mathcal{M}_1, T_1)$ and $(\mathcal{M}_2, T_2)$ as in Theorem 3.6 are called *isomorphic* if there exists a matrix $S \in \mathrm{GL}_2(K)$ with

$$S^{-1}\mathcal{M}_1 = \mathcal{M}_2 \quad \text{and} \quad S^T T_1 S' = T_2.$$

Isomorphic pairs yield the same moduli subspace inside $\mathcal{A}_2$, and to prove Theorem 1.1, it suffices to show that the number of isomorphism classes of pairs $(\mathcal{M}_i, T_i)$ is finite.

If σ is an automorphism of K , then also $(\mathcal{M}, T)$ and $(\sigma\mathcal{M}, \sigma T)$ yield the same moduli space. Hence, given K and $x \in K$ we can describe all principally polarized abelian surfaces $A/\mathbf{C}$ admitting an endomorphism x with $\mathbf{Q}[x] = K$ by listing the isomorphism classes of pairs $(\mathcal{M}_i, T_i)$ up to this action of $\mathrm{Aut}(K)$.

First assume that $K = \mathbf{Q}[x]$ is a quadratic field. Depending on K and $(\mathcal{M}, T)$ we either get a surface, a curve or a point in the moduli space.

4.1. Real quadratic fields.

Lemma 4.1. *Let $K = \mathbf{Q}[x]$ be real quadratic and let $\mathcal{O} = \mathbf{Z}[x]$ be an order in K . Let $(\mathcal{M}, T)$ be a pair consisting of an $\mathcal{O}$ -submodule $\mathcal{M}$ of K^2 that is free of rank 4 as a $\mathbf{Z}$ -module and a matrix $T \in \mathrm{GL}_2(K)$ that satisfies the conditions of Lemma 3.4. Then, up to isomorphism, we have*

$$\mathcal{M} = \mathcal{O}_1 \oplus \mathcal{O}_1 \quad \text{and} \quad T = \delta(\mathcal{O}_1)^{-1} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

where $\mathcal{O}_1 \supset \mathcal{O}$ is an order of K and $\delta(\mathcal{O}_1) = 2\alpha - \mathrm{Tr}\alpha$ generates the different of $\mathcal{O}_1 = \mathbf{Z}[\alpha]$.

Proof. Let $(\mathcal{M}, T)$ be a pair consisting of an $\mathcal{O}$ -module of $\mathbf{Z}$ -rank 4 and a matrix T satisfying the conditions of Theorem 3.6. As $\mathcal{O}$ is quadratic, every ideal is generated by 2 elements as a $\mathbf{Z}$ -module, hence in particular as an $\mathcal{O}$ -module. By Bass [1, Prop. 1.5], this implies that every finitely generated projective $\mathcal{O}$ -module is the direct sum of ideals of $\mathcal{O}$. For $\mathcal{M}$ of rank 4 over $\mathbf{Z}$, this implies (after a suitable choice of basis) $\mathcal{M} = \mathfrak{a} \oplus \mathfrak{b}$ for fractional (not necessarily invertible) $\mathcal{O}$ -ideals $\mathfrak{a}, \mathfrak{b}$.

By Example 3.5, we know that T is of the form

$$\begin{pmatrix} 0 & c \\ -c & 0 \end{pmatrix}$$

for some $c \in K^*$. We derive that $\mathfrak{a}$ has trace dual $\mathfrak{a}^\dagger = \mathfrak{b}c$, and as a consequence we see that $\mathfrak{a}$ and $\mathfrak{b}$ have the same multiplier ring $\mathcal{O}_1$. An argument similar to [13, Prop. 3.4] shows that we have $\mathfrak{a}\mathfrak{b}c = \delta(\mathcal{O}_1)^{-1}$, and $\mathfrak{b}$ therefore equals $(\delta(\mathcal{O}_1)c\mathfrak{a})^{-1}$ as $\mathcal{O}_1$ -ideal. Without loss of generality, we may therefore assume that we have $\mathfrak{a} = \mathcal{O}_1$ and hence $\mathfrak{b}c = \mathcal{O}_1^\dagger = (1/\delta(\mathcal{O}_1))\mathcal{O}_1$. Then after scaling we get $\mathcal{M} = \mathcal{O}_1 \times \mathcal{O}_1$ and $c = 1/\delta(\mathcal{O}_1)$, which proves the lemma. $\square$

Corollary 4.2. *Let l be prime. Then the variety $\mathcal{M}_2^{(l,l)}$ contains exactly two irreducible Humbert surfaces for $l \equiv 1 \pmod{4}$ and exactly one irreducible Humbert surface otherwise.*

Proof. The ring $\mathbf{Z}[\sqrt{l}]$ has index 2 in the maximal order of $K = \mathbf{Q}(\sqrt{l})$ for $l \equiv 1 \pmod{4}$ and equals the maximal order otherwise. By Lemma 4.1 and Theorem 3.6, we get two surfaces for $l \equiv 1 \pmod{4}$: one surface for $\mathcal{M} = \mathbf{Z}[\sqrt{l}]^2$ and one for $\mathcal{M} = \mathcal{O}_K^2$. In the other case, we find only one $\mathcal{M}$ and hence only one Humbert surface.

Alternatively, this result is the special case $t = 1$ of [24, Thm. IX.2.4], which states that the Humbert surface H_D of discriminant D is irreducible for every quadratic discriminant D . For $D = 4l$ prime with $l \equiv 1 \pmod{4}$, this gives one component $H_{D/4}$ and one component H_D . For $D \equiv 4l$ with $l \not\equiv 1 \pmod{4}$, we have only the irreducible surface H_D . $\square$

4.2. Imaginary quadratic fields. The situation is similar for *imaginary* quadratic fields K : we again have to list all pairs $(\mathcal{M}, T)$ for the order $\mathcal{O} = \mathbf{Z}[x]$. We may proceed analogously to the proof of Lemma 4.1 and write $\mathcal{M} = \mathfrak{a} \oplus \mathfrak{b}$ for fractional $\mathbf{Z}[x]$ -ideals $\mathfrak{a}, \mathfrak{b}$. However, since we have less control over the matrix T , we cannot derive that $\mathcal{M} = \mathcal{O}_1 \oplus \mathcal{O}_1$ for an order $\mathcal{O}_1 \supset \mathcal{O}$ in this case.

For $\mathcal{O} = \mathbf{Z}[x]$, let $\delta(\mathcal{O}) = 2x - \text{Tr}(x)$ be the different of $\mathcal{O}$. Then, for the matrix $S = \delta T$, the condition $\overline{T}^T = -T$ is equivalent to

$$\overline{S}^T = S,$$

in other words, to S being *Hermitian*. There seems to be a lot of theory related to the classification of pairs $(\mathcal{M}, S)$ that one could try to apply to the problem of enumerating these pairs. For example, Hayashida-Nishi [8] computes the class number of pairs $(\mathcal{M}, S)$ with S positive definite, Shimura [20] computes the class number of pairs where $\mathcal{M}$ is a so-called “maximal lattice”, and we will see below how to associate to S the structure of a quaternion algebra on $\mathcal{M} \otimes \mathbf{Q}$, making $\mathcal{M}$ into an ideal for an order B in this quaternion algebra, and one might hope to use results on class numbers of B . However, such results all require $\mathcal{O}$ (or possibly even B) to be a maximal order. General results that do not require maximal orders seem to be lacking, hence we will give a more direct approach below.

Lemma 4.3. *If $\mathcal{M} \supset \mathcal{O} \times \mathcal{O}$, then we have $[\mathcal{M} : \mathcal{O} \times \mathcal{O}] = \pm \det S$.*

Proof. The determinant of $E : (u, v) \mapsto \text{Tr}_{K/\mathbf{Q}}(u^T T v')$ with respect to a $\mathbf{Z}$ -basis of $\mathcal{O} \times \mathcal{O}$ can be computed to be $(\det S)^2$. With respect to a $\mathbf{Z}$ -basis of $\mathcal{M}$, it therefore equals $[\mathcal{M} : \mathcal{O} \oplus \mathcal{O}]^{-2} (\det S)^2$. On the other hand, as the polarization is principal, this determinant is known to be 1, which proves Lemma 4.3. $\square$

Applying complex conjugation to $(\mathcal{M}, T)$ if needed, we may assume that S is not negative definite. Write $\Phi(u, v) = u^T S v'$ and $\mu(u) = \Phi(u, u)$. We distinguish two cases: the case where μ takes the value 0 on $\mathcal{M}$ and the case where it doesn't.

If μ does not take the value 0. Take a K -basis b_1, b_2 of $\mathcal{M} \otimes \mathbf{Q}$ with $b_1, b_2 \in \mathcal{M}$, and choose this basis such that $|\mu(b_1)|$ is minimal over all $b_1 \in \mathcal{M}$, and $|\mu(b_2)|$ is minimal among all $b_2 \in \mathcal{M}$ that satisfy $\Phi(b_1, b_2) = 0$.

Let $a = \mu(b_1)$ and $b = \mu(b_2)$, and identify $\mathcal{M} \otimes \mathbf{Q}$ with K^2 via the basis b_1, b_2 .

Lemma 4.4. *We have*

(1)

$$\mathcal{O} \times \mathcal{O} \subset \mathcal{M} \subset \left(\frac{1}{a}\mathcal{O}\right) \times \left(\frac{1}{b}\mathcal{O}\right),$$

where for both inclusions the index is $|ab|$.

(2)

$$1 \leq |a| \leq t \frac{2d(\mathcal{O})^{1/2}}{\pi} \quad \text{and} \quad |a| \leq |b| \leq 4td(\mathcal{O})^{3/2}/\pi^2 + \frac{4 + d(\mathcal{O})}{4},$$

with $t = 1$ if S is indefinite, and $t = 2$ if S is definite.

Proof. Note that $b_1 = (1, 0)^T$ and $b_2 = (0, 1)^T$ are in the $\mathcal{O}$ -module $\mathcal{M}$, hence $\mathcal{M} \supset \mathcal{O} \times \mathcal{O}$. Now take any element $(u, v)^T$ in $\mathcal{M}$. Then we have $au = \Phi(u, b_1) \in \mathcal{O}$ and $bv = \Phi(u, b_2) \in \mathcal{O}$, which proves the inclusions in (1). The index of both inclusions is $|ab|$ by Lemma 4.3.

The body

$$V = \{(u, v)^T \in \mathbf{C}^2 : \max\{|a|u\overline{u}, |b|v\overline{v}\} \leq B\}$$

is closed, convex and symmetric of volume $\pi^2 B^2 / |ab|$, which for $B = 2d(\mathcal{O})^{1/2}/\pi$ is equal to $4[\mathcal{M} : \mathcal{O} \times \mathcal{O}]^{-1} d(\mathcal{O}) = 16\text{covol}(\mathcal{M})$. By Minkowski's convex body theorem, this implies that $V \cap \mathcal{M}$ contains a non-zero element $z = (u, v)^T$. We find $|\mu(z)| = |au\overline{u} + bv\overline{v}| \leq tB$, hence by choice of b_1 also $|a| \leq tB$.

Finally, let

$$W = \{(u, v)^T \in \mathbf{C}^2 : |\operatorname{Re}(u)| < \frac{1}{|a|}, |\operatorname{Im}(u)| < \frac{d(\mathcal{O})^{1/2}}{2|a|}, |b|v\bar{v} \leq C\},$$

so

$$\operatorname{vol}(W) = 2\pi \frac{d(\mathcal{O})^{1/2}C}{a^2|b|},$$

which for $C = 2tBd(\mathcal{O})/\pi = 4td(\mathcal{O})^{3/2}/\pi^2$ is equal to $4d(\mathcal{O})/|ab| \cdot tB/|a| \geq 16\operatorname{covol}(\mathcal{M})$. By Minkowski's convex body theorem, this implies that $V \cap \mathcal{M}$ contains a non-zero element $z = (u, v)^T$. We find $|\mu(z)| = |au\bar{u} + bv\bar{v}| \leq C + a\frac{4+d(\mathcal{O})}{4a^2} \leq C + \frac{4+d(\mathcal{O})}{4}$, hence by choice of b_2 , the number $|b|$ is below this bound, which proves part (2). $\square$

If μ takes the value 0. Let $b_1 \in \mathcal{M}$ with $\mu(b_1) = 0$ be such that $zb_1 \in \mathcal{M}$ for $z \in K$ implies $|z| \geq 1$. Then take $b_2 \in \mathcal{M}$ such that $a = \Phi(b_1, b_2) \in \mathcal{O}$ has minimal absolute value among all b_2 linearly independent of b_1 , and such that $b = \mu(b_2) \in \mathbf{Z}$ has minimal absolute value among all b_2 for the given value of a .

Identify $\mathcal{M} \otimes \mathbf{Q}$ with K^2 via the K -basis b_1, b_2 .

Lemma 4.5. *We have*

- (1) $\mathcal{M} \supset \mathcal{O} \times \mathcal{O}$ with index $N(a)$,
- (2)

$$1 \leq N(a) \leq \pi^{-2}d(\mathcal{O}) \quad \text{and} \quad |b| \leq \frac{1}{2}|\operatorname{Tr}_{K/\mathbf{Q}}(a)| \leq |a|$$

Proof. As the basis elements $b_1 = (1, 0)$ and $b_2 = (0, 1)$ are in $\mathcal{M}$, so is $\mathcal{O} \times \mathcal{O}$. By Lemma 4.3, the index is $\pm \det S$. As we have $-\det S = N(a) > 0$, this proves (1).

Let $V = \{(u, v) \in \mathbf{C}^2 : N(u), N(v) < 1\}$, which has volume π^2 and note that $\mathcal{M} \subset \mathbf{C}^2$ has covolume

$$\frac{d(\mathcal{O})}{4[\mathcal{M} : \mathcal{O} \times \mathcal{O}]} = \frac{d(\mathcal{O})}{4N(a)}.$$

By Minkowski's convex body theorem, if $\pi^2 > d(\mathcal{O})/N(a)$, then there exists a non-zero $z = ub_1 + vb_2 \in \mathcal{M}$ with $N(u), N(v) < 1$. Now $v = 0$ contradicts minimality of b_1 , hence z is linearly independent of b_1 and $0 < N(u) < 1$ contradicts minimality of b_2 . This proves $\pi^2 \leq d(\mathcal{O})/N(a)$, which gives our upper bound on $N(a)$.

By translation of b_2 via a $\mathbf{Z}$ -multiple of b_1 , we can always get $|b| \leq \frac{1}{2}|\operatorname{Tr}_{K/\mathbf{Q}}(a)|$. $\square$

Example 4.6. Let $K = \mathbf{Q}(\sqrt{-2})$ and let $x \in K$ satisfy $\mathcal{O}_K = \mathbf{Z}[x]$. Since $\mathcal{O}_K$ has class number 1, the only projective $\mathbf{Z}[x]$ -submodule of rank 2 of $K \times K$ up to $\operatorname{GL}_2(K)$ -equivalence is

$$\mathcal{M} = \mathcal{O}_K \times \mathcal{O}_K.$$

We want to find a complete set of representatives for the set of matrices $T \in \operatorname{GL}_2(K)$ that fit into a pair $(\mathcal{M}, T)$, up to isomorphism and complex conjugation of that pair.

Let $\delta = (x - \bar{x}) = 2\sqrt{-2}$ denote the different of $\mathcal{O}_K$. Let $S = \delta T$ be the Hermitian matrix corresponding to T . In this situation, we can use the technique of [8, §5] instead of the method of the current section. We find that

$$T_1 = \frac{1}{\delta} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad T_2 = \frac{1}{\delta} \begin{pmatrix} 2 & \sqrt{-2} + 1 \\ -\sqrt{-2} + 1 & 2 \end{pmatrix}$$

are representatives of the two isomorphism classes for positive definite S . Each corresponds to a point in the moduli space.

We find that there are exactly two isomorphism classes with $\det S < 0$, and they are represented by

$$T_3 = \frac{1}{\delta} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \quad \text{and} \quad T_4 = \frac{1}{\delta} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

each yielding a Shimura curve.

4.3. Degree-4 CM-fields. Let K be a degree-4 CM-field, and fix an order $\mathcal{O} \subset K$ with $\overline{\mathcal{O}} = \mathcal{O}$.

We want to enumerate the isomorphism classes of pairs $(\mathcal{M}, T)$, where $\mathcal{M} \subset K$ is an $\mathcal{O}$ -module of rank 4 over $\mathbf{Z}$ and $T = (\xi)$ is a 1×1 -matrix such that

- (1) ξ^2 is totally negative;
- (2) the bilinear form $E : \mathcal{M} \times \mathcal{M} \rightarrow \mathbf{Q}$ given by $E(x, y) = \text{Tr}_{K/\mathbf{Q}}(\xi \overline{xy})$ has image $\mathbf{Z}$ and determinant 1.

Recall that we call $(\mathcal{M}_1, \xi_1)$ isomorphic to $(\mathcal{M}_2, \xi_2)$ if and only if there exists $u \in K^*$ satisfying $u^{-1}\mathcal{M}_1 = \mathcal{M}_2$ and $u\overline{u}\xi_1 = \xi_2$.

The fact that the image of the bilinear form is in $\mathbf{Z}$ is equivalent to the inclusion of $\mathcal{O}$ -ideals $\xi\overline{\mathcal{M}} \subseteq \mathcal{M}^*$, where $\mathcal{M}^*$ is the dual of $\mathcal{M}$ for the trace form $(x, y) \mapsto \text{Tr}_{K/\mathbf{Q}}(xy)$. The determinant of E is 1 if and only if this inclusion is an equality, so we need to enumerate pairs $(\mathcal{M}, \xi)$ satisfying $\xi\overline{\mathcal{M}} = \mathcal{M}^*$, up to isomorphism. This observation is a generalization of Theorems 3.13 and 3.14 of [22]. After we have listed all pairs $(\mathcal{M}, \xi)$, we can use e.g. the techniques from [25] to construct an algebraic model for the abelian variety corresponding to $(\mathcal{M}, \xi)$.

We now show how to compute the set of pairs $(\mathcal{M}, \xi)$ up to isomorphism. For any fractional $\mathcal{O}$ -ideal $\mathcal{M}$, write $\mathcal{M}_K = \mathcal{M} \otimes_{\mathcal{O}} \mathcal{O}_K$. If e denotes the exponent of the abelian group $\mathcal{O}_K/\mathcal{O}$, then for every $\mathcal{M}$, we have $e\mathcal{M}_K \subseteq \mathcal{M} \subseteq \mathcal{M}_K$. As a first step, we compute a complete set C of representatives of the class group of the maximal order $\mathcal{O}_K$ of K . For any $\mathcal{N} \in C$, it is a finite computation to find all $\mathcal{M}$ with $\mathcal{M}_K = \mathcal{N}$. This gives us a complete set of representatives of the ideals $\mathcal{M}$ up to multiplication by K^* .

The next step is to find all possibilities for ξ for each $\mathcal{M}$. Let $\mathcal{O}(\mathcal{M}) = \{x \in K : x\mathcal{M} \subseteq \mathcal{M}\}$ be the multiplier ring of $\mathcal{M}$ and let K_0 be the real quadratic subfield of K . For every pair $(\mathcal{M}, \xi)$, we have

$$\begin{aligned} \xi\overline{\mathcal{M}_K} &\supseteq \xi\overline{\mathcal{M}} = \mathcal{M}^* \supseteq \mathcal{M}_K^* = \mathcal{M}_K^{-1}\mathcal{D}_{K/\mathbf{Q}}^{-1} \quad \text{and} \\ e\xi\overline{\mathcal{M}_K} &\subseteq \xi\overline{\mathcal{M}} = \mathcal{M}^* \subseteq e^{-1}\mathcal{M}_K^* = e^{-1}\mathcal{M}_K^{-1}\mathcal{D}_{K/\mathbf{Q}}^{-1}, \end{aligned}$$

so for every valuation v of K , we have

$$-2v(e) \leq v(\xi) + v(\mathcal{M}_K\overline{\mathcal{M}_K}\mathcal{D}_{K/\mathbf{Q}}) \leq 0.$$

This gives finitely many candidate ideals $\xi\mathcal{O}_K$. For each, we can check whether it is principal and generated by an element $\xi \in K$ such that ξ^2 is totally negative. If so, let U be a complete set of representatives of those classes $\overline{u}$ in the finite group $\mathcal{O}_{K_0}^*/N_{K/K_0}(\mathcal{O}(\mathcal{M})^*)$ for which $(\mathcal{M}, u\xi)$ satisfies (1) and (2) above. The pairs $(\mathcal{M}, u\xi)$ cover all isomorphism classes.

4.4. The main Theorem. In this section we put all the theory developed up to now into action and give a proof of Theorem 1.1.

Proof of Theorem 1.1. Fix a prime l , and let $A \in \mathcal{M}_2^{(l,l)}$ be a principally polarized abelian surface. For an (l,l) endomorphism $x : A \rightarrow A$ we write $K = \mathbf{Q}[x]$. There are two possibilities: K is a field or it is not.

If K is *not* a field, Lemma 3.1 gives restrictions on x . Using the notation of this lemma, we note that there are only finitely many pairs (β_1, β_2) of imaginary quadratic elements of complex absolute value $\sqrt{l}$. For each pair, there are finitely many isomorphism classes of complex elliptic curves E_i with $\text{End}(E_i) \supseteq \mathbf{Z}[\beta_i]$. Finally, for each pair of curves (E_1, E_2) there are finitely many possibilities for the kernel of λ . This means that there are only *finitely* many choices for (isomorphism classes of) pairs (A, x) . These choices correspond to case (5) of Theorem 1.1.

Now suppose that K is a field. First we show that there are only finitely many possibilities for K . By Lemma 3.2, the degree of $K/\mathbf{Q}$ divides four and the Rosati involution equals complex conjugation on $K \subset \mathbf{C}$. If there exists a real embedding, then we have $K = \mathbf{Q}(\sqrt{l})$. Otherwise, K is a CM-field of degree two or four. In both cases, x is a non-real algebraic integer and $x + x'$ is in every real absolute value less than $2\sqrt{l}$, which implies that the set of possible K 's is finite.

Theorem 3.6 associates to every pair $(\mathcal{M}, T)$, consisting of a $\mathbf{Z}[x]$ -submodule of $K^{m(K)}$ and a matrix $T \in \text{GL}_2(K)$ with $(T')^T = -T$, a moduli space $S(\mathcal{M}, T) \subset \mathcal{A}_2$. The surface A is contained in some space $S(\mathcal{M}, T)$ and, conversely, for every $(\mathcal{M}, T)$ we have $S(\mathcal{M}, T) \subset \mathcal{M}_2^{(l,l)}$. Hence, it remains to show that there are only finitely many isomorphism classes of pairs $(\mathcal{M}, T)$.

For real quadratic K , the number of pairs $(\mathcal{M}, T)$ correspond to the number of orders $\mathbf{Z}[x] \subseteq \tilde{\mathcal{O}} \subseteq \mathcal{O}_K$. It is classical that there are only finitely many such orders $\tilde{\mathcal{O}}$. This is case (1) of Theorem 1.1 and the proof follows from Theorem 3.6 and Corollary 4.2 above.

For imaginary quadratic K , Lemmas 4.5 and 4.4 bound the index $[\mathcal{M} : \mathbf{Z}[x] \times \mathbf{Z}[x]]$ in terms of the discriminant of $\mathbf{Z}[x]$. This implies that there are only finitely many choices for $\mathcal{M}$. The matrix T is

$$\delta^{-1} \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix} \quad \text{or} \quad \delta^{-1} \begin{pmatrix} 0 & a \\ a' & b \end{pmatrix}$$

respectively for the cases of Lemmas 4.4 and 4.5. These are cases (2) and (3) of Theorem 1.1.

Finally, assume that K is a degree-4 CM-field. This is case (4) of Theorem 1.1. Section 4.3 gives an algorithm for explicitly computing all pairs $(\mathcal{M}, T) = (\mathcal{M}, (\xi))$ and we show that this approach terminates in a finite amount of time. Going through the computations done in the algorithm, we note that since the class group of $\mathcal{O}_K$ is finite, there are only finitely many ideal classes $\mathcal{N}$. For any $\mathcal{N}$, there are only finitely many $\mathcal{M}$ with $\mathcal{M} \otimes_{\mathcal{O}} \mathcal{O}_K = \mathcal{N}$ because we can restrict to those $\mathcal{M}$ satisfying $e\mathcal{N} \subseteq \mathcal{M} \subseteq \mathcal{N}$, where the exponent e of $\mathcal{O}_K/\mathcal{O}$ is finite. Hence, there are only finitely many choices for $\mathcal{M}$. As explained in Section 4.3, the valuations of ξ are bounded, so there are only finitely many choices for the principal $\mathcal{O}_K$ -ideal generated by ξ . $\square$

5. ENDOMORPHISM RINGS, AND DECOMPOSITIONS INTO ELLIPTIC CURVES

Next, we recall the endomorphism rings corresponding to each of the cases mentioned above. For details, see [19] or [2, Exercises 9.10(3) and (4)].

In some cases, we can use this information to write our abelian surfaces as glueings. In the remaining cases, we can use it to write our Shimura curves as components of intersections of Humbert surfaces.

If S is definite, then the endomorphism x acts on V by multiplication by a complex number β . Any decomposition of $\mathcal{M} \otimes \mathbf{Q}$ as $K \times K$ yields a decomposition of $V = \mathcal{M} \otimes \mathbf{R}$ into 1-dimensional complex subspaces V_1 and V_2 . We find elliptic curves $E_i = V_i / (V_i \cap \mathcal{M})$ and an isogeny $E_1 \times E_2 \rightarrow A$, which allows us to find A by *glueing* (see Section 6) elliptic curves with endomorphism ring containing $\mathbf{Z}[x]$. Moreover, we find that $\text{End}(A) \otimes \mathbf{Q}$ contains $\text{Mat}_2(K)$, which acts on $\mathcal{M} \subset K \times K$. In fact, the ring $\text{End}(A)$ equals the set of elements of $\text{Mat}_2(K)$ that multiply $\mathcal{M}$ into itself. We give an example of this construction in the proof of Lemma 7.1.

If S is indefinite, then we give $B = \mathcal{M} \otimes \mathbf{Q}$ a quaternion algebra structure induced by S as defined by e.g. [20]. This quaternion algebra structure is easiest described by choosing a K -basis of B that diagonalizes S as

$$\begin{pmatrix} 1 & 0 \\ 0 & s \end{pmatrix}.$$

Denote the first basis element of B by 1 and the second by ρ , so elements of B are written as $x + y\rho$ with $x, y \in K$. Then B becomes a quaternion algebra with $\rho^2 = -s > 0$, $\rho u = \overline{u}\rho$ for $u \in K$. The quaternion algebra B comes equipped with a positive definite involution $\dagger$ given by $(x + y\rho)^\dagger = \overline{x} + y\rho$.

The quaternion algebra B acts on $\mathcal{M} \otimes \mathbf{Q}$ (that is, on itself) by left multiplication, and Shimura showed that this induces an embedding $\iota : B \rightarrow \text{End}(A) \otimes \mathbf{Q}$. Moreover, the Rosati-involution on $\text{End}(A)$ induces $\dagger$ on B , and $R = \iota^{-1}(\text{End}(A))$ consists exactly of those elements of B that map $\mathcal{M}$ to itself.

If we now take a maximal real quadratic subring $R_1 \subset R$ on which $\dagger$ is trivial, then the Shimura curve corresponding to $(\mathcal{M}, S)$ is contained in the Humbert surface of R_1 . If we take two such subrings R_1 and R_2 with non-isomorphic fraction fields, then the intersection of the corresponding Humbert surfaces is a finite union of irreducible curves, and one of these curves is our Shimura curve.

We will not need to do the construction above for the case where x is a $(2, 2)$ -isogeny, because we can then always use the following construction.

Suppose still that S is indefinite. Then μ takes the value 0 if and only if B is $\text{Mat}_2(\mathbf{Q})$. If this is the case, then the symmetric idempotents of B show that A is isogenous to a product of elliptic curves E and F , and the structure of B gives rise to an isogeny $E \rightarrow F$. The degree d of this isogeny is constant on our Shimura curve. In particular, the candidate pairs (E, F) are parametrized by the modular polynomial Φ_d , and we can obtain A from Φ_d via glueing techniques. We give an example of this construction in the proof of Lemma 7.2.

6. GLUEINGS

In this section we recall how to *glue* two elliptic curves to obtain a Jacobian of a genus-2 curve. Glueing is a method for explicitly exhibiting abelian surfaces that are (n, n) -isogenous to a given pair of elliptic curves. This will enable us to explicitly

compute the abelian surfaces that occur for $K = \mathbf{Q}[x]$ imaginary quadratic or not a domain. We will illustrate this method for $n = 2$ in the next section.

6.1. Glueing Elliptic Curves. Let E_1 and E_2 be complex elliptic curves and let $n \in \mathbf{Z}_{>1}$ be an integer. Let $\psi : E_1[n] \xrightarrow{\sim} E_2[n]$ be an *anti-isometry* with respect to the Weil pairing, i.e., an isomorphism such that $e_n(\psi(P), \psi(Q)) = e_n(P, Q)^{-1}$ holds for all $P, Q \in E_1[n]$. If ψ is an anti-isometry, then $\text{graph } \psi$ is maximally isotropic with respect to the Weil pairing on $(E_1 \times E_2)[n]$. By Lemma 2.5, this implies that $\text{graph } \psi$ is the kernel of an (n, n) -isogeny to a unique principally polarized abelian variety $A = (E_1 \times E_2)/\text{graph } \psi$. We say that we *glue* E_1 and E_2 along their n -torsion via ψ and call the (n, n) -isogeny $E_1 \times E_2 \rightarrow A$ an n -glueing.

The following shows that glueings are a very general kind of (n, n) -isogenies.

Lemma 6.1. *Let E_1, E_2 be elliptic curves and n a prime number. Then every (n, n) -isogeny $E_1 \times E_2 \rightarrow A$ for any A is either an n -glueing or of the form $E_1 \times E_2 \rightarrow (E_1/C_1) \times (E_2/C_2)$ for $C_i \subset E_i$ of order n .*

Proof. It suffices to prove that every isotropic subgroup $\Gamma \subset E_1 \times E_2$ with $\Gamma \cong (\mathbf{Z}/n\mathbf{Z})^2$ is either of the form $C_1 \times C_2$ or is the graph of an anti-isometry $E_1 \rightarrow E_2$.

There are $(n^4 - 1)/(n - 1)$ maximally isotropic subgroups by Lemma 2.5, of which

$$((n^2 - 1)/(n - 1))^2 = n^2 + 2n + 1$$

are products $C_1 \times C_2$ and $(n^2 - 1)n = n^3 - n$ are graphs of anti-isometries. As we have $(n^4 - 1)/(n - 1) = (n^2 + 2n + 1) + (n^3 - n)$, this covers all cases. $\square$

Some glueings are the Jacobian of a genus-2 curve. In fact, we have the following result.

Theorem 6.2 (Kani [10, Thm. 3]). *Let (E_1, E_2, n, ψ) be as above Lemma 6.1 and assume n is prime. Then the glueing associated to this pair is the Jacobian of a genus-2 curve if and only if there do not exist an integer k strictly between 0 and l and an isogeny $h : E_1 \rightarrow E_2$ of degree $k(n - k)$ with the property*

$$h|_{E_1[n]} = k \circ f.$$

We can explicitly write down algebraic equations for glueings for small primes n . The case $n = 2$ goes back to Legendre. Explicit constructions for $n = 3$ are more recent [11] and the case $n = 5$ is still actively studied [18]. We recall the constructions for $n = 2, 3$ in the remainder of this section.

6.2. 2-glueing. We now make the case $n = 2$ more explicit. We follow Serre's explanation [17, Sec. 27] of Legendre's method. Let $(E_1, E_2, n = 2, \psi)$ be as above and write each curve E_i in the form $E_i : y^2 = g_i$ for a cubic polynomial $g_i \in \mathbf{C}[x]$. We see that the double cover $E_1 \rightarrow \mathbf{P}^1$ given by the x -coordinate has four ramification points, which are exactly the points in $E_1[2] = \{P_1, P_2, P_3, P_4\}$. Let $Q_j = f\psi(P_j)$ and apply a fractional linear transformation of the x -coordinate of E_2 to get $x(Q_j) = x(P_j)$ for $j = 1, 2, 3$.

Remark 6.3. *By Theorem 6.2, the glueing corresponding to $(E_1, E_2, 2, \psi)$ as above is the Jacobian of a curve of genus 2 if and only if ψ is not of the form $h|_{E_1[2]}$ for an isomorphism $h : E_1 \rightarrow E_2$, that is, if and only if $x(Q_4)$ and $x(P_4)$ are distinct.*

Assume that we have $x(Q_4) \neq x(P_4)$. Let K_1 and K_2 be the function fields of E_1 and E_2 as quadratic extensions of $\mathbf{Q}(x)$ and let K_{12} be their composite. Let $K_0 \subset K_{12}$ be the other intermediate extension of degree 2. The field K_0 is ramified over $\mathbf{Q}(x)$ only at $x(P_4)$ and $x(Q_4)$, so K_0 has genus 0. The extension K_{12}/K_0 is ramified in the 6 places of K_0 lying over the three points $x(P_j)$ for $j = 1, 2, 3$. In particular, it follows from the Riemann-Hurwitz genus formula that the curve C with function field K_{12} has genus 2. The Jacobian of C is $(2, 2)$ -isogenous to $E_1 \times E_2$ via an isogeny with kernel graph ψ .

In terms of equations, Legendre's glueing construction can be described as follows. Choose a Legendre model of E_1 so that we have $x(P_1) = \infty$, $x(P_2) = 0$, $x(P_3) = 1$ and let $a = x(P_4)$. As above we have $x(Q_j) = x(P_j)$ for $j = 1, 2, 3$. Let $b = x(Q_4) \neq a$, so E_1 and E_2 are given by

$$E_1 : y^2 = x(x-1)(x-a), \quad E_2 : y^2 = x(x-1)(x-b).$$

The curve C_0 with function field K_0 is given by $C_0 : y^2 = (x-a)(x-b)$ and has a parametrization

$$t \mapsto \left(x = a + \frac{(a-b)t^2}{1-t^2}, \quad y = \frac{(a-b)t}{1-t^2} \right).$$

The extension K_{12}/K_0 ramifies at the points with $x \in \{\infty, 0, 1\}$, i.e., with $t^2 \in \{1, a/b, (a-1)/(b-1)\}$. In particular, the genus-2 curve $C = C(a, b)$ obtained by glueing E_1 and E_2 as above is:

$$C(a, b) : s^2 = (t^2 - 1)(t^2 - \frac{a}{b})(t^2 - \frac{a-1}{b-1}).$$

6.3. 3-glueing. In [11, Example 6], Kuhn studies 3-glueings and gives an example of a family of genus-2 curves C such that $J(C)$ is the image of a $(3, 3)$ -isogeny from a product of elliptic curves. The curve

$$C : y^2 = (x^3 + ax^2 + bx + c)(4cx^3 + b^2x^2 + 2bcx + c^2)$$

is a 3-glueing of two elliptic curves with j -invariants

$$j(E_1) = \frac{16(972ac^3 - 405b^2c^2 - 216a^2bc^2 + 126ab^3c - 12b^5 - a^2b^4)^3}{(27c^2 - b^3)^3(27c^2 - 18abc + 4a^3c + 4b^3 - a^2b^2)^2}$$

$$j(E_2) = \frac{256(3b - a^2)^3}{27c^2 - 18abc + 4a^3c + 4b^3 - a^2b^2}.$$

We will use these formulas in our calculations in the next section.

7. THE CASE OF $(2, 2)$ -ENDOMORPHISMS

In this section, we give all principally polarized abelian surfaces that have a $(2, 2)$ -isogeny to themselves. We use the computer algebra package MAGMA [3] to help us with the computations. We give some of them in terms of a hyperelliptic model of the form $y^2 = f(x)$, and others in terms of their homogeneous Igusa invariants I_2, I_4, I_6, I_{10} (denoted A, B, C, D by Igusa [9] and A', B', C', D' by Mestre [15]). Mestre's algorithm [15] computes a hyperelliptic model from these Igusa invariants.

We start by introducing short notation for the elliptic curves and curves of genus 2 that appear in our lists. If D is a negative quadratic discriminant and $h(D)$ is the class number of the order $\mathcal{O}_D$ of discriminant D , let $E_D^1, \dots, E_D^{h(D)}$ be the isomorphism classes of elliptic curves over $\mathbf{C}$ with endomorphism ring $\mathcal{O}_D$. If

$h(D) = 1$, then we denote E_D^1 also by E_D . Table 1 on page 16 defines a list of curves of genus 2 in terms of their Igusa invariants I_2, I_4, I_6, I_{10} . All curves in the table are isogenous to a product of elliptic curves. In fact, these curves have a subscript D or D_1, D_2 in their notations, and these subscripts indicate that their Jacobian is isogenous to $E_D^1 \times E_D^1$ or $E_{D_1}^1 \times E_{D_2}^1$.

Now that we have the notation for our output, let us compute all abelian surfaces with a $(2, 2)$ -endomorphism x . In the case $\mathbf{Z}[x] = \mathbf{Z}[\sqrt{2}]$, we know from Lemma 4.1 that there is only a single Humbert surface H_8 , which is computed by Gruenewald [7]. Now suppose $\mathbf{Z}[x]$ is imaginary quadratic. We start with the case where the Hermitian form S of Section 4.2 is definite.

Lemma 7.1. *Let A be a principally polarized abelian surface over $\mathbf{C}$ and $x : A \rightarrow A$ a $(2, 2)$ -isogeny. If $\mathbf{Z}[x]$ is imaginary quadratic and S of Section 4.2 is definite, then A is isomorphic to one of $E_{-4} \times E_{-4}, E_{-7} \times E_{-7}, E_{-8} \times E_{-8}$, and $J(C_{-8})$.*

Proof. Example 3.3 shows that $\mathbf{Z}[x]$ is the maximal order of the imaginary quadratic field of discriminant $D \in \{-4, -7, -8\}$. By replacing (M, T) by its complex conjugate, we may assume that S is *positive* definite.

The case $D = -8$ is the positive definite case of Example 4.6, which yields $E_{-8} \times E_{-8}$ and exactly one other abelian surface. We will now construct that abelian surface. With respect to the basis $\frac{1}{2}, \frac{1}{2}\sqrt{-2} \pmod{\mathbf{Z}[\sqrt{-2}]}$ of $E_{-8}[2]$, we have

$$\sqrt{-2} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \text{and we define } \psi = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}.$$

Let $g : E_{-8} \times E_{-8} \rightarrow A = E_{-8} \times E_{-8} / (\text{graph } \psi)$ be the glueing of E_{-8} with itself along ψ . Multiplication by $x = \sqrt{-2}$ on $E_{-8} \times E_{-8}$ sends $\text{graph } \psi$ to itself because ψ and $\sqrt{-2}$ commute on $E_{-8}[2]$. In particular, the endomorphism x induces an endomorphism $g x g^{-1} \in \text{End}(A)$. The fact that both x and the quotient map g are $(2, 2)$ -isogenies implies that $g x g^{-1}$ is also a $(2, 2)$ -isogeny.

Using the formula of Section 6.2, we find $A = J(C_{-8})$ with C_{-8} as in Table 1.

The cases $D = -4$ and $D = -7$ are analogous to Example 4.6, but yield only $E_D \times E_D$, because there is only one positive definite isomorphism class of pairs (M, S) . $\square$

TABLE 1. A list of genus-2 curves and the homogeneous Igusa invariants that define them.

Lemma 7.2. *Let A be a principally polarized abelian surface over $\mathbf{C}$. There exists a $(2, 2)$ -isogeny $x : A \rightarrow A$ with $\mathbf{Z}[x]$ imaginary quadratic and S indefinite, if and only if A is a point on one of the following Shimura curves:*

- (1) *the curve in $\mathcal{A}_2$ of which the points are the products $E \times E$ of an elliptic curve E with itself;*
- (2) *the curve in $\mathcal{A}_2$ of which the points are the products $E \times F$ for all 2-isogenies $E \rightarrow F$;*
- (3) *the Zariski closure of the image of the map $\mathbf{C} \setminus \{0, 1\} \rightarrow \mathcal{A}_2$ given by $u \mapsto C(u, 1 - u)$, where $C(u, v)$ is given as in Section 6.2 by*

$$C(a, b) : y^2 = (x^2 - 1)(x^2 - \frac{b}{a})(x^2 - \frac{b-1}{a-1});$$

- (4) *the Zariski closure of the image of the map $\mathbf{C} \setminus \{-1, 0, 1\} \rightarrow \mathcal{A}_2$ given by*

$$u \mapsto C(u^2, \frac{(u-1)^2}{(u+1)^2});$$

- (5) *the Zariski closure of the image of the map $X \rightarrow \mathcal{A}_2 : (u, v) \mapsto C(u, v)$, where $X \subset \mathbf{A}^2$ is given by Figure 1 on page 18.*

Each of these 5 Shimura curves has genus 0.

Proof. As in the proof of Lemma 7.1, the ring $\mathbf{Z}[x]$ is the maximal order of the imaginary quadratic field of discriminant $D = -4, -7$, or -8 . This time, the case $D = -8$ is the indefinite case of Example 4.6. We find six Shimura curves, each corresponding to $\mathcal{M} = \mathbf{Z}[x] \times \mathbf{Z}[x]$ and

$$T = T_3 = \frac{1}{\delta} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \quad \text{or} \quad T = T_4 = \frac{1}{\delta} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

Note that T_3 and T_4 are equivalent for odd D , so that we actually have only five distinct Shimura curves, which we will now compute.

Let $f : E \rightarrow F$ be a degree- n isogeny of elliptic curves. If $a, b \in \mathbf{Z}$ are such that $a^2 + b^2n = l$, then we have an (l, l) -isogeny

$$x = \begin{pmatrix} a & bf' \\ -bf & a \end{pmatrix} \in \text{End}(E \times F)$$

such that $\mathbf{Z}[x]$ is quadratic of discriminant $D = -4b^2n$. Indeed, we have $x^2 - 2ax + l = 0$ and $x' = 2a - x$, hence $x'x = l$.

The products $E \times F$ form a curve $\mathcal{S}$ in the moduli space $\mathcal{A}_2$, and that curve $\mathcal{S}$ is covered by the modular curve $Y_0(n)$ of n -isogenies $E \rightarrow F$. Any such $\mathcal{S}$ is contained in one of the Shimura curves we are looking for. By the construction in [2, §9.6], the Shimura curves are irreducible, so that $\mathcal{S}$ is in fact equal to one of the Shimura curves.

We apply the above to $l = 2$, $D = -4$, $n = a = b = 1$, $F = E$, $f = \text{id}_E$, which yields the Shimura curve of all squares $E \times E$ of elliptic curves E . We also apply it to $l = 2$, $D = -8$, $n = 2$, $a = 0$, $b = 1$, which yields the Shimura curve of all products $E \times F$ for which F is 2-isogenous to E . We have now found 2 of our 5 Shimura curves.

We will find more Shimura curves by looking at (k, k) -isogenies $g : E \times F \rightarrow A$ for small k and checking if the element $gxg^{-1} \in \text{End}_{\mathbf{Q}}(A)$ (with x as above) is in $\text{End}(A)$. As in the proof of Lemma 7.1, the fact that g is a (k, k) -isogeny and x

The curve $X \subset \mathbf{A}^2$ given by

$$\begin{aligned}
X : \quad & a, b \notin \{0, 1\}, \\

\end{aligned}$$

has genus 2. It is birational to the fibered product $Y_0(7) \times_{Y(1)} Y(2)$ parametrizing tuples (E, F, ψ, P_1, P_2) up to isomorphism, where $\psi : E \rightarrow F$ is a 7-isogeny and P_1, P_2 form a basis of $E[2]$. The birational map $X \rightarrow Y_0(7) \times_{Y(1)} Y(2)$ is given by $(a, b) \mapsto (\psi, P_1, P_2)$, where $E : y^2 = x(x-1)(x-a)$, $P_1 = (0, 0)$, $P_2 = (1, 0)$, $F : y^2 = x(x-1)(x-b)$ and $f : E \rightarrow F$ is a 7-isogeny.

FIGURE 1. The curve X of Lemma 7.2.

is an (l, l) -isogeny imply that the induced endomorphism $gxg^{-1} \in \text{End}(A)$ is an (l, l) -isogeny.

The condition that gxg^{-1} is in $\text{End}(A)$ is equivalent to the condition that x maps $\ker(g)$ to itself. In particular, if $\ker(g)$ is the graph of an anti-isometry $\psi : E[k] \rightarrow F[k]$, then gxg^{-1} is in $\text{End}(A)$ if and only if

$$(7.1) \quad b(\psi f' \psi + f) = 0$$

holds on $E[k]$.

For the case $D = -4$ (again with $l = 2$, $n = a = b = 1$, $F = E$, $f = \text{id}_E$), write $E : y^2 = x(x-1)(x-u)$ and choose the basis $(0, 0), (1, 0)$ of $E[2]$. Let ψ be the automorphism of $E[2]$ that swaps these basis elements. The fractional linear transformation of the x -coordinate sending ∞ to itself and swapping 0 and 1 maps E to $y^2 = x(x-1)(x-v)$ with $v = 1-u$. Therefore, we find $E \times E/(\text{graph } \psi) \cong J(C(u, 1-u))$ as in Section 6.2.

For the case $D = -8$ (with $n = l = 2$, $a = 0$, $b = 1$), recall from [21, Ex. X.4.8] that every 2-isogeny $f : E \rightarrow F$ can be written in the form

$$E : y^2 = x(x-1)(x-a^2), \quad F : y^2 = x(x-1)\left(x - \left(\frac{1-a}{1+a}\right)^2\right)$$

with $\ker f = \langle (0, 0) \rangle$, $\ker f' = \langle (0, 0) \rangle$ and $a \in \mathbf{C} \setminus \{-1, 0, 1\}$. The map $\psi : E[2] \rightarrow F[2]$ given by $(0, 0) \mapsto (0, 0)$ and $(1, 0) \mapsto (1, 0)$ satisfies $\psi f' \psi = f$ and we find curve (4).

For the only remaining Shimura curve (with $D = -7$), we apply the above to $l = 8$, $D = -28$, $n = 7$, $a = b = 1$. Let $f : E \rightarrow F$ be a 7-isogeny and let $\psi_j = f|_{E[j]} : E[j] \rightarrow E[j]$. Let $A = E \times F / (\text{graph } \psi_2)$ and let g be the quotient map. We need to show that $\frac{1}{2}gxg^{-1}$ is an endomorphism of A , i.e. that x maps $[2]^{-1} \text{graph } \psi_2$ to $\text{graph } \psi_2$. Choose a basis of $E[4]$. As f has odd degree, the image of this basis under f is a basis of $E[4]$.

We have $2^{-1} \text{graph } \psi_2 = \text{graph } \psi_4 + (E[2] \times 0)$. Given $P \in E[4]$, we find $x(P, \psi_4(P)) = (P + f'\psi_4P, -fP + \psi_4P) = (8P, 0) = 0$. Let $P \in E[2]$ be any element. We find $x(P, 0) = (P, -fP) = (P, fP) \in \text{graph } \psi_2$. This shows that indeed x maps $[2]^{-1} \text{graph } \psi_2$ to $\text{graph } \psi_2$.

Next, let X be the set of triples $x = (f, P_1, P_2)$ consisting of a 7-isogeny $f : E \rightarrow F$ and a basis P_1, P_2 of the 2-torsion of E . We will compute a model for the modular curve X , together with the glueing map to $\mathcal{A}_2$.

As before, let $Y_0(l)$ be the modular curve of l -isogenies $f : E \rightarrow F$. Let $Y(l)$ be the modular curve of elliptic curves E together with a basis of the l -torsion. We have natural maps $\pi_E, \pi_F : X \rightarrow Y(2)$, given by $\pi_E(x) = (E, P_1, P_2)$ and $\pi_F(x) = (F, f(P_1), f(P_2))$, and natural maps $\pi_E, \pi_F : Y_0(l) \rightarrow Y(1) = \mathbf{A}^1$, given by $\pi_E : f \mapsto j(E)$ and $\pi_F : f \mapsto j(F)$. See also Figure 2 on page 19. In fact, $Y_0(l)$ is exactly the zero-locus of the modular polynomial $\Phi_l \in \mathbf{Z}[X, Y]$ when X and Y are π_E and π_F .

Next, we have $Y(2) = \mathbf{C} \setminus \{0, 1\}$, where $a \in \mathbf{C} \setminus \{0, 1\}$ corresponds to the elliptic curve $y^2 = x(x-1)(x-a)$ with the basis $(0, 0), (1, 0)$ of the 2-torsion. To glue E to F along $\text{graph } f|_{E[2]}$ for all $x \in X$, we need a description of X from which $a = \pi_E(f)$ and $b = \pi_F(f)$ can be read off. This means that we want a description of X as a subvariety of $Y(2) \times Y(2)$. We have the natural map $j : Y(2) \rightarrow Y(1)$ given by $j(a) = 2^8(a^2 - a + 1)^3(a - 1)^{-2}a^{-2}$. Let $W = (j \times j)^{-1}(Y_0(7))$, so $X \subset W \subset Y(2) \times Y(2)$ and W is the zero locus of $P = \Phi_7(j(u), j(v)) \in \mathbf{Q}(u, v)$.

We factor the numerator of P using MAGMA as a product of 6 irreducible polynomials in $\mathbf{Q}[u, v]$. Note $W = \sqcup_{\sigma} X^{\sigma}$, where $\sigma \in \text{Aut}(F[2])$ acts by changing

FIGURE 2. The curves X , $Y(2)$, $Y(1)$ and $Y_0(7)$ from the proof of Lemma 7.2.

the basis of $F[2]$. As $\text{Aut}(F[2])$ has order 6, we find that X is the zero locus of exactly one of the 6 factors of the numerator of P .

To select the correct factor, we now prove that S is a subset of the Humbert surface H_8 . Let

$$y = \begin{pmatrix} 1 & f' \\ f & -1 \end{pmatrix}, \quad \text{so} \quad \frac{1}{2}(x - y) = \begin{pmatrix} 0 & 0 \\ -f & 1 \end{pmatrix}.$$

We compute that $g\frac{1}{2}(x - y)g^{-1}$ (and hence $g\frac{1}{2}yg^{-1}$) is an endomorphism of A . We have $y' = y$ and $(\frac{1}{2}y)^2 = 2$, hence $S \subset H_8$. Using the defining equation for H_8 from [7], we find that exactly one out of our 6 candidates for S lies on H_8 , so we know that this is the correct one.

Now only the statement about the genus remains. The first two Shimura curves are birational to $Y(1)$ and $Y_0(2)$, which are known to have genus 0. The third and fourth are defined as the image of a rational map from $\mathbf{P}^1$, hence also have genus 0. We used MAGMA to compute that the genus of S is also 0. $\square$

A *Weil q -number* is an algebraic integer π such that $\pi\bar{\pi} = q$ for every embedding of π into $\mathbf{C}$.

Lemma 7.3. *If $K = \mathbf{Q}[x]$ is a quartic CM-field and x is a Weil 2-number, then the characteristic polynomial P_x^a is an irreducible polynomial of degree 4 of the form*

$$f = X^4 - a_1X^3 + (4 + a_2)X^2 - 2a_1X + 4,$$

where a_1 and a_2 are integers.

Tables 2 and 3 list exactly the possible pairs (a_1, a_2) (up to replacing x by $-x$ and a_1 by $-a_1$) such that f is irreducible and its roots satisfy $x\bar{x} = 2$, together with all complex principally polarized abelian surfaces of which the endomorphism ring contains a subring isomorphic to $\mathbf{Z}[X]/f$. The Galois group of the field $\mathbf{Q}[X]/f$ is $C_2 \times C_2$ for f as in Table 2 and D_4 for f as in Table 3.

Proof. Suppose x is a Weil 2-number of degree 4 and let $\beta = x + 2/x = x + \bar{x}$, so β is a totally real algebraic integer of degree at most 2. As we have $x^2 - \beta x + 2 = 0$,

TABLE 3. All Weil 2-numbers that generate quartic fields that do not contain an imaginary quadratic subfield are roots of $f = X^4 - a_1X^3 + (4 + a_2)X^2 - 2a_1X + 4$ with a_1, a_2 as in the table. For each such Weil 2-number x , the principally polarized abelian surfaces over $\mathbf{C}$ of which the endomorphism ring contains x are exactly the Jacobians of the curves of genus 2 of which the Igusa invariants are listed next to the values of a_1 and a_2 .

we find that β is not rational. Let a_1 be the trace of the real quadratic integer β and a_2 its norm. Then f as in the lemma is the minimal polynomial of x . As x is non-real, we find that $\beta^2 - 8$ is totally negative, which gives upper bounds on the absolute values of a_1 and a_2 . For all a_1, a_2 up to those bounds with $a_1 \geq 0$, we checked if f is irreducible and its roots are Weil 2-numbers.

For each resulting a_1, a_2 where $K = \mathbf{Q}[x]$ is a quartic CM-field that does not contain an imaginary quadratic subfield, it turned out that $\mathbf{Z}[x, \bar{x}]$ is its ring of integers, and an algorithm to compute Table 3 is given in [23].

For the remaining cases, where $K = \mathbf{Q}[x]$ does contain an imaginary quadratic subfield, the precision needed for the complex analytic method as in [23] is not known, so we have to resort to alternative methods. The method of Section 4.3 gives at least one representative of each isomorphism class of principally polarized abelian varieties with the endomorphism x .

This already allows us to compute Table 2 by numerical approximation, without guarantee of correctness, using the same techniques as in [23].

To get a proof of the entries in the table, let ϕ_1, ϕ_2 be the two embeddings $K \rightarrow \mathbf{C}$ that map ξ to the positive imaginary axis. Let $K_1 \subset K$ be the unique imaginary quadratic subfield such that ϕ_1 and ϕ_2 are equal on K_1 . Then A is isogenous to the square $E \times E$ of an elliptic curve E with CM by the ring of integers $\mathcal{O}_{K_1}$ of K_1 (see [12, Theorem 1.3.5] or see the definite case in the discussion of Section 5). We can thus prove Table 2 by glueing techniques. $\square$

Lemma 7.4. *Let A be a principally polarized abelian surface over $\mathbf{C}$ and $x : A \rightarrow A$ a $(2, 2)$ -isogeny. If $\mathbf{Q}[x]$ is not a field, then A is one of the following:*

- (1) *the 5 polarized products $E_{-4} \times E_{-4}$, $E_{-4} \times E_{-7}$, $E_{-4} \times E_{-8}$, $E_{-7} \times E_{-7}$ and $E_{-7} \times E_{-8}$,*
- (2) *the Jacobians of the 4 curves C_{-7} , $C_{-4, -8}$, and $C_{-4, -7}^a$, where $a^2 = 7$.*

Conversely, each of these abelian surfaces has such an endomorphism x .

Proof. Given A and x , let E_1, E_2, n, λ be as in Lemma 3.1. As we can interchange E_1 and E_2 , and we can replace x by $\pm x$ or $\pm \bar{x}$, we have without loss of generality $\text{Tr}\beta_1 > \text{Tr}\beta_2$, $|\text{Tr}\beta_1| \geq |\text{Tr}\beta_2|$, and $\text{Im}\beta_1 > 0$.

Example 3.3 shows that $\mathbf{Z}[\beta_j]$ is the maximal order of the imaginary quadratic field of discriminant $-4, -7$, or -8 , which has class number 1. Therefore, we get exactly one curve E_j for a given β_j and hence (1) lists exactly all examples with $n = 1$.

Now assume n is minimal with the properties of Lemma 3.1, and suppose that $n \neq 1$. Let $p|n$ be a prime and let $S = \ker \lambda \cap (E_1 \times E_2)[p]$. As λ is an (n, n) -isogeny, its kernel is maximally isotropic in $(E_1 \times E_2)[n]$ by Lemma 2.5. This implies that S is maximally isotropic in $(E_1 \times E_2)[p]$. By Lemma 6.1, it follows that S is either a product $C_1 \times C_2$ of subgroups $C_j \subset E_j[p]$ of order p , or S is the graph of an anti-isometry $\psi : E_1[p] \rightarrow E_2[p]$. Moreover, as (β_1, β_2) induces an endomorphism of A , it sends $\ker \lambda$ to itself and hence sends S to S .

Note that $S = C_1 \times C_2$ is not possible. Indeed, it would imply that E_j/C_j has CM by $\mathbf{Z}[\beta_j]$ and that we have an $(n/p, n/p)$ -isogeny

$$E_1/C_1 \times E_2/C_2 = (E_1 \times E_2)/S \rightarrow (E_1 \times E_2)/\ker \lambda = A,$$

contradicting minimality of n .

Therefore, S is the graph of an anti-isometry $\psi : E_1[p] \rightarrow E_2[p]$, and the fact that (β_1, β_2) sends S to itself implies that $\beta_2 \circ \psi = \psi \circ \beta_1$ holds on $E_1[p]$.

Let $T = (\text{Tr} \beta_1 \bmod p) = (\text{Tr} \beta_2 \bmod p) \in \mathbf{Z}/p\mathbf{Z}$. We find that we are in one of the following cases:

- (1) $\beta_1 = 1 + i, \beta_2 = \pm i\sqrt{2}, p = n = 2, T = 0$,
- (2) $\beta_1 = 1 + i, \beta_2 = \frac{1}{2}(-1 \pm i\sqrt{7}), p = n = 3, T = -1$,
- (3) $\beta_1 = 1 + i, \beta_2 = -1 \pm i, p = 2, n \in \{2, 4\}, T = 0$,
- (4) $\beta_1 = \frac{1}{2}(1 + i\sqrt{7}), \beta_2 = \frac{1}{2}(-1 \pm i\sqrt{7}), p = n = 2, T = 1$.

We can dismiss case 3, and the special case of 4 where $\text{Im} \beta_2 < 0$, because of the following argument. In those cases, we identify E_1 with E_2 and find that $\beta_2 - \beta_1$ is a multiple of 2 in the endomorphism ring of E_1 , hence (β_1, β_2) and (β_1, β_1) are equal on $(E_1 \times E_2)[2]$, showing that (β_1, β_1) induces an endomorphism of $(E_1 \times E_2)/S$ with both eigenvalues of the analytic representation equal to β_1 . By Lemma 7.1 this implies that $(E_1 \times E_2)/S \cong E_1 \times E_2$ as a polarized abelian variety, contradicting minimality of n .

In case 1, the difference $\beta_2 - \overline{\beta_2}$ is a multiple of 2, so the above argument shows that the two possible signs lead to the same set of abelian surfaces. Therefore, we can restrict to $\text{Im} \beta_2 > 0$ in this case without loss of generality.

Only the cases 1, 2, and 4 remain and in each of these cases except case 2, we can assume $\text{Im} \beta_2 > 0$. The group

$$E_j[p] = (\mathbf{C}/\mathbf{Z}[\beta_j])[p] = \frac{1}{p}(\mathbf{Z}[\beta_j]/p\mathbf{Z}[\beta_j]),$$

has a basis $1/p, \beta_j/p$ and we express β_j and ψ by matrices with respect to these bases. The identity $\beta_2\psi = \psi\beta_1$ puts some restrictions on the coefficients of ψ . Moreover, the Weil pairing e_p on $E_j[p]$ satisfies $e_p(1/p, \beta_j/p) = \exp(\pm(2\pi i)/p)$, where the sign is the sign of the imaginary part of β_j . In particular, the map ψ is an anti-isometry if and only if its determinant is $\pm(-1)$ in $\mathbf{Z}/p\mathbf{Z}$. We now have a system of equations for the coefficients of ψ , which we solve.

For case 1, we find 2 solutions, which yield isomorphic quotients $(E_1 \times E_2)/S$, since the groups S are mapped to each other by $\text{Aut}(E_1 \times E_2) = \text{Aut}(E_1) \times \text{Aut}(E_2)$. Glueing techniques show that the quotient is $J(C_{-4, -8})$. For case 4, we find 1 solution, which yields $J(C_{-7})$.

Only case 2 remains. We find 4 solutions with $\text{Im } \beta_2 > 0$ and 4 solutions with $\text{Im } \beta_1 < 0$. Each of these sets of 4 solutions is an $\text{Aut}(E_1 \times E_2)$ -orbit, so that there are at most 2 quotient abelian surfaces.

Section 6.3 gives Kuhn's parametrization of a set of curves C of genus 2 such that $J(C)$ is the image of a $(3, 3)$ -isogeny from a product of elliptic curves. As this parametrization includes a formula for the j -invariants of E_1 and E_2 , we can solve for $j(E_2) = 1728$ and $j(E_1) = -3375$. This yields equations for 6 pairwise non-isomorphic curves C of genus 2 of which the Jacobian is the image of a $(3, 3)$ -isogeny from $E_1 \times E_2$.

We claim that this list of 6 curves contains all curves C such that $J(C)$ is $(3, 3)$ -isogenous to $E_1 \times E_2$. Indeed, the kernel of the isogeny $E_1 \times E_2 \rightarrow J(C)$ is the graph of an anti-isometry by Lemmas 2.5 and 6.1. There are 24 anti-isometries from $E_1[3]$ to $E_2[3]$, which are partitioned into 6 orbits of composition with $\mathbf{Z}[i]^*$ on the right, hence the list of candidate curves is complete.

The points in $\mathcal{A}_2$ corresponding to these candidate curves are partitioned into two Galois orbits over $\mathbf{Q}$: one of length 2 and one of length 4. As we have found only two possibilities $A = (E_1 \times E_2)/\text{graph}(\psi)$, and isomorphism classes of endomorphism rings over $\mathbf{C}$ are invariant under conjugation over $\mathbf{Q}$, our two A cannot lie in the Galois orbit of length 4, so they form the Galois orbit of length 2. They are the $C_{-4,-7}^a$ listed in the lemma. Using the generators for W_2 computed in [5], we easily check that $C_{-4,-7}$ indeed lies in the space W_2 . $\square$

We now state and prove a more explicit version of Theorem 1.2.

Theorem 7.5. *The reduced variety $\mathcal{M}_2^{(2,2)}$ is the disjoint union of the Humbert surface H_8 of discriminant 8, which is irreducible, and the following 12 CM points:*

- (1) $E_{-4} \times E_{-7}, E_{-4} \times E_{-8}, E_{-7} \times E_{-8}$,
- (2) $C_{-15}, C_{-4,-8}, C_{-4,-7}^a$ ($a^2 = 7$), and
- (3) the 6 CM points corresponding to the curves with $a_1 = 1$ of Table 3.

Proof. The variety $\mathcal{M}_2^{(2,2)}$ is the union of H_8 , the Shimura curves of Lemma 7.2, and the CM points of Lemmas 7.1, 7.3, and 7.4. For any elliptic curve E , we have $E \times E \in H_8$ because of the endomorphism

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

The same holds for any product $E \times F$ where $f : E \rightarrow F$ is a 2-isogeny, because of

$$\begin{pmatrix} 0 & f' \\ f & 0 \end{pmatrix}.$$

This proves that the first two Shimura curves of Lemma 7.2 are on H_8 , as well as all of the polarized products of Lemma's 7.1 and 7.3, and 2 of the 5 polarized products of Lemma 7.4. The remaining three polarized products don't lie on the Humbert surface since their endomorphism rings are direct products of rings without $\sqrt{2}$, hence we list those in (1).

This leaves only the last three Shimura curves of Lemma 7.2 and the Jacobians in Tables 1 and 3. For these, we could compute the endomorphism rings by looking at their constructions, as we did for the polarized products. However, it is much easier to evaluate the equation of H_8 (given in [7]) in their Igusa invariants to decide whether they lie on H_8 . Of Table 1, it turns out that all curves are points on the

Humbert surface, except the three listed in (2). Of Table 3, only two curves are points on the Humbert surface, and the other six are listed in (3). $\square$
